

The invention is a soap container with a lid that is designed to attached to a typical faucet that is opened and closed via a valve that is opened or closed by moving a handle a quarter of a turn.

The soap container apparatus is preferably rectangular in shape having a plurality of  
5 holes at short axis end and an attachment mechanism at the other end short axis end. The plurality of holes is designed for draining the water left from the use of the soap. The attachment mechanism of the soap container is provided with a groove shaped and sized according to its insertion in the external upper section of the threaded shaft of the valve that permits said valve to opened or closed. The soap container with a lid is fixed to the faucet of the type mentioned above  
10 by a flat lid and female threaded ridge round shaped fixing element.

### **BRIEF DESCRIPTION OF THE DRAWINGS**

FIG. 1 illustrates a side view of the soap container apparatus attached to a valve of a faucet in accordance with the invention.

FIG. 2 illustrates a perspective exploded view of the components of the soap container  
15 apparatus showing the opened lid and its location with respect to the valve of the faucet.

### **DETAILED DESCRIPTION OF THE INVENTION**

Fig. 1 illustrates the invention in the preferred embodiment. In the figures described above, similar reference numerals indicate similar or corresponding parts, in which reference numeral 1 indicates a typical valve which can opened or closed by a quarter of a turn; reference  
20 numeral 2 indicates the soap container apparatus with a lid; reference numeral 3 indicates a plurality of drainage holes; reference numeral 4 indicates a circular flat lid and female threaded ridge fixing element; reference numeral 5 indicates a ridge with a groove shaped and sized according to tap 1; reference numeral 6 indicates a male threaded stem; reference numeral 7 indicates hinges.

25 As shown in Fig. 2, the preferred shape of the soap container apparatus is rectangular; however, other shapes such as oval, round, even triangular are acceptable. At the shorter axis

end of rectangular shaped soap container apparatus 2 are a plurality of drainage holes 3 designed for draining the water left from the use of a bar of soap (not shown) are provided. On the opposite end, an outer ridge 5 is provided with a groove shaped and sized according to its insertion in the external upper section of the threaded shaft of the valve 1. The soap container apparatus 2 is fixed to valve 1 of the type discussed above by a flat lid 4 which has female thread that can be screwed onto the male threaded stem 6 of valve 1.

The handle or turning element (not shown) of valve 1 which is supplied by the manufacturer for closure or opening thereof in order is removed. The soap container apparatus 2 is attached via groove 5 to the male threaded stem 6, to subsequently hold in place via a fixing element which is a round flat lid and female threaded ridge 4.

Due to this attachment, when the user turns the soap container 2, to either side, the faucet via valve is opened or closed respectively and the soap is kept when closing the lid of the soap container with lid 2.

If desired, the manufacturer supplied handle (not shown) can be reinstalled by easily removing soap container apparatus 2 by unscrewing fixing element 4 from valve 1 and then reattaching the handle on male threaded stem 6.

The illustrated embodiments of the invention are intended to be illustrative only, recognizing that persons having ordinary skill in the art may construct different forms of the invention that fully fall within the scope of the subject matter disclosed herein. Other features and advantages of the invention will be apparent from the descriptions hereof.
